

For a high-performance PC dedicated to intense gaming and seamless live streaming, I would choose a **liquid cooling system** for the GPU. Streaming graphics-heavy games pushes both the GPU and CPU to their limits for hours at a time, generating immense, sustained heat that can cause traditional air coolers to thermal throttle and drop frame rates. Liquid cooling provides superior thermal dissipation, keeping the graphics card significantly cooler and ensuring a stable, stutter-free broadcast for viewers. Additionally, liquid setups run much quieter under heavy loads, preventing loud fan noise from being picked up by my streaming microphone.
