

When you open a desktop PC cabinet, you will find several interconnected hardware components that work together to make the system function. Here are the main internal components and their descriptions:

- **Motherboard:** The massive main circuit board that acts as the backbone of the PC, physically connecting and allowing communication between all other components.
- **Central Processing Unit (CPU):** Often called the "brain" of the computer, it executes instructions, processes data, and runs the operating system and applications.
- **CPU Cooler:** A dedicated heatsink and fan (or liquid block) mounted directly on top of the CPU to dissipate the massive amount of heat it generates.
- **Random Access Memory (RAM):** The computer's ultra-fast, short-term memory that temporarily holds data currently in use by active games and programs.
- **Graphics Processing Unit (GPU) / Video Card:** A specialized expansion card dedicated entirely to rendering visuals, 3D graphics, and video output to your monitor.
- **Storage Drives (SSD or HDD):** The permanent storage where your operating system, games, software, and personal files are saved—with modern Solid State Drives (SSDs) being much faster than older Hard Disk Drives (HDDs).
- **Power Supply Unit (PSU):** A heavy metal box that converts alternating current (AC) electricity from your wall outlet into regulated direct current (DC) power for the internal hardware.
- **Case Fans:** System fans attached to the front, top, or rear panels of the cabinet to pull in cool air and exhaust hot air, maintaining proper overall airflow.
